

# SE 102 Abstract Data Type and Problem Solving Lecture 1

Asst Prof. Pree Thiengburanathum, PhD.

[pree.t@cmu.ac.th](mailto:pree.t@cmu.ac.th)

Office room 415-1

# Agenda

- ~~Course Syllabus~~
- Java Fundamentals
  - Compiling Java (new JDK and JRE)
  - Comment, identifiers and variable names
  - Primitive data types
  - Method
  - One dimensional array and multi-dimensional array

# Course Syllabus

- Can be retrieved from Moodle

# Compiling a Java program

- Eclipse or VSCode as integrated development environment (IDE)
  - Download and install Eclipse IDR for Java Developers
    - [www.eclipse.org](http://www.eclipse.org), <https://code.visualstudio.com/>
- Compile using *javac* and run via command line
  - <https://introcs.cs.princeton.edu/java/15inout/windows-cmd.html>
- Compile java source code online (covid 19 effected student)
  - <https://www.compilejava.net/>
  - <https://www.jdoodle.com/online-java-compiler>
  - <http://rextester.com/l/java> online compiler

# Java comments

Each comment line in Java begins with

`"/**"`  
and ends with  
`"*/`

A one-line comment begins with `"//"`

```
/**  
 * Hello1 --- program to print "Hello World".  
 * @author   Pree T.  
 */  
public class Hello1 {  
 :  
}
```

# Java comments

```
1 // Counts the number of occurrences of the provided name
2 // in the given list of names.
3 //
4 // Pre
5 // - The list of names must not be null, otherwise an IllegalArgumentException
6 //   will be thrown.
7 // - The target name must not be null, otherwise an IllegalArgumentException
8 //   will be thrown.
9 //
10 // Post
11 // - Returns the number of times targetName appears in names as a positive int.
12 public static int numberOfOccurrences(List<String> names, String targetName) {
13     int count = 0;
14     for (String name : names) {
15         if (name.equals(targetName)) {
16             count += 1;
17         }
18     }
19     return count;
20 }
```

# Identifiers and variable names in Java

- *Identifiers* are the names of **variables**, **methods**, **classes**, **packages** and **interfaces**. Unlike literals they are not the things themselves, just ways of referring to them.
- In the HelloWorld program, HelloWorld, String, args, main and println are identifiers.
- My Variable           // Contains a space
- 9pins                 // Begins with a digit
- a+c                  // The plus sign is not an alphanumeric character
- testing1-2-3        // The hyphen is not an alphanumeric character
- O'Reilly            // Apostrophe is not an alphanumeric character
- OReilly\_&\_Associates // ampersand is not an alphanumeric character

# Data Type

- Data Type
  - a data type is a set of values together with an associated collection of operators for manipulating those values.
- 2 types of data type
  - ~~Primitive data type i.e. int, double, char, boolean, floating point~~
  - Defined data type i.e. array, list

# Java operators

Operator	Description	Example
+ (Addition)	Adds values on either side of the operator.	A + B will give 30
- (Subtraction)	Subtracts right-hand operand from left-hand operand.	A - B will give -10
* (Multiplication)	Multiplies values on either side of the operator.	A * B will give 200
/ (Division)	Divides left-hand operand by right-hand operand.	B / A will give 2
% (Modulus)	Divides left-hand operand by right-hand operand and returns remainder.	B % A will give 0
++ (Increment)	Increases the value of operand by 1.	B++ gives 21
-- (Decrement)	Decreases the value of operand by 1.	B-- gives 19

# Primitive data type `int`

Integers can be both positive and negative

A subset of real number

- The `/` operator denotes integer division
  - $a/b$  evaluates to  $a$  divided by  $b$ , discarding any remainder
  - $5/2$  evaluates to 2
  - $-23/6$  evaluates to  $-3$
  - $4/43$  has the value 0
- The expression  $a\%b$  evaluates to the remainder of  $a$  divided by  $b$ 
  - $5\%2$  has the value 1
  - $-23\%3$  has the value  $-2$

# Primitive data type **double**

- The values are decimal numbers in the range  $-1.7 \times 10^{308}$ ...  $1.7 \times 10^{308}$  with 14 significant digits of accuracy.
- The division operator (/) denotes decimal or floating point division rather than integer division; so 5.0/2.0 has the value 2.5 but 5/2 has the value 2

# Primitive data type `char`

- Type *char* is the set of all characters found on the standard keyboard
- Java uses the Unicode character set and allocates two bytes of memory for each character.
- Using two bytes allows 65,536 characters.
- In java, A value of type `char` is enclosed in single quotes:
- `'5'` is a value of type `char`,
- `"5"` is a string literal, and
- `5` is an integer.

# Java operator precedence

- `int x = 4 + 3 * 5;`
- 1. `(4 + 3) * 5 == 35`
- 2. `4 + (3 * 5) == 19`
- In the absence of parentheses, which choice is appropriate?
- In the case of Java, multiplication takes precedence over addition; therefore, x will get the value 19.
- [http://www.cs.bilkent.edu.tr/~guvenir/courses/CS101/op\\_precedence.htm](http://www.cs.bilkent.edu.tr/~guvenir/courses/CS101/op_precedence.htm)  
!

# Primitive data type **boolean**

- Type boolean has two values: true and false
- The associated operators:
- '&&' --'and'
- '||' --'or'
- '!' --'not'

# The truth table

Copyright © The McGraw-Hill Companies, Inc. Permission required for reproduction or display.

<b>x</b>	<b>y</b>	<b>x &amp;&amp; y (and)</b>	<b>x    y (or)</b>	<b>!x (not)</b>
true	true	true	true	false
true	false	false	true	false
false	true	false	true	true
false	false	false	false	true

# Methods

- A *method* is a named sequence of instructions that are grouped together to perform a task.
- Methods enable the programmer to organize various tasks into neat manageable independent *bundles* of code

# Methods

- Every Java application must have a main method
- The execution of every Java application begins with the main method.
- Other methods that we have used are print(...), println(...),

# Java's Pre-defined Methods

- Imagine a mathematical “*black box*” that works in such a way that whenever you supply a number to the box
- The box gives or returns the positive square root of that number.

# Java's Pre-defined Methods

- A similar mechanism that accepts *two* numbers, the *length* and *width* of a rectangle, and returns the area of the rectangle.

# 4 formats of Method

- void method1 ()
- void method1(arg1,arg2.., argn)
- returned type method1()
- returned type method1(arg1,arg2.., argn)

# Method example

```
/** the snippet returns the minimum between two numbers */
```

```
public static int minFunction(int n1, int n2) {  
    int min;  
    if (n1 > n2)  
        min = n2;  
    else  
        min = n1;  
  
    return min;  
}
```

# Method example (cont.)

```
public class ExampleMinNumber {  
  
    public static void main(String[] args) {  
        int a = args[0];  
        int b = 6;  
        int c = minFunction(a, b);\br/>        System.out.println("Minimum Value = " + c);  
    }  
}
```

[DEMO](#)

# Array

- An array is a collection of **elements, items, or values** that have the same data type.
- Unlike the variables of previous programs, an array can store *more than one* value.

# A variable in contrast to an array

# Array Instantiation

- Once an array is created, its length is *fixed*.
- The length of an array cannot be *altered*.
- If variable x refers to an array, then x.length gives the number of memory cells allocated to the array.

# Creating Arrays

- General syntax for declaring an array:

```
Base_Type[] Array_Name = new Base_Type[Length];
```

- Examples:

80-element array with base type char:

```
char[] symbol = new char[80];
```

100-element array of doubles:

```
double[] reading = new double[100];
```

70-element array of Species:

```
Species[] specimen = new Species[70];
```

# The = operator

- $b=a$

- After the assignment  $b=a$

# The = operator

- `B[0] = 100;`

- After executing the assignment `b=a`, the references `a` and `b` both refer to the **same memory** and any changes to `a[i]` **affect** `b[i]`;

# One dimension array

**// Declaration of allocating memory to an array**

```
int iarr[] = new int[3];
```

**// Initializing elements**

```
iarr[0] = 1;
```

```
iarr[1] = 2;
```

```
iarr[2] = 3;
```

# One dimensional array

**//Display array elements**

```
System.out.println(iarr[0]);  
System.out.println(iarr[1]);  
System.out.println(iarr[2]);
```

**// Or Use for loop to display elements**

```
for (int i = 0; i < iarr.length; i = i + 1)  
{  
    System.out.print(iarr[i]);  
    System.out.print(" ");  
}
```

# Multidimensional Arrays

	Column 0	Column 1	Column 2	Column 3
Row 0	<code>a[ 0 ][ 0 ]</code>	<code>a[ 0 ][ 1 ]</code>	<code>a[ 0 ][ 2 ]</code>	<code>a[ 0 ][ 3 ]</code>
Row 1	<code>a[ 1 ][ 0 ]</code>	<code>a[ 1 ][ 1 ]</code>	<code>a[ 1 ][ 2 ]</code>	<code>a[ 1 ][ 3 ]</code>
Row 2	<code>a[ 2 ][ 0 ]</code>	<code>a[ 2 ][ 1 ]</code>	<code>a[ 2 ][ 2 ]</code>	<code>a[ 2 ][ 3 ]</code>

Diagram illustrating the structure of a two-dimensional array with three rows and four columns. The array is represented as a grid of elements, each labeled with its row and column indices (e.g., `a[ 0 ][ 0 ]` for the first element in the first row). The columns are labeled "Column 0", "Column 1", "Column 2", and "Column 3". The rows are labeled "Row 0", "Row 1", and "Row 2". Arrows point from the labels "Column index", "Row index", and "Array name" to the corresponding parts of the element notation `a[ 2 ][ 1 ]` in the third row, second column.

Two-dimensional array with three rows and four columns.

# Creating Two-dimensional Arrays

- Can be created dynamically

- 3-by-4 array

```
int b[][];  
b = new int[ 3 ][ 4 ];
```

- Rows can have different number of columns

```
int b[][];  
b = new int[ 2 ][ ];  
// create 2 rows  
b[ 0 ] = new int[ 5 ];  
// create 5 columns for row 0  
b[ 1 ] = new int[ 3 ];  
// create 3 columns for row
```

# Q&A
